Homogeneous catalysis

♣ Acid and base catalysis
♣ The mechanisms of some catalysed reactions
♣ Catalysis by non-covalent binding

（5 学时）

The rates of many organic reactions are enhanced by the presence of catalysis, species which do not themselves appear in the products but which in various way assist the progress of the reaction.

Fig. 9.1 Schematic energy profile for uncatalysed (A) and acid-catalysed (B) reactions in which a substrate, S, is converted to a product, P. S, substrate; P, product; E_A, principal energy barrier for an uncatalysed reaction; E_b, principal energy barrier for a catalysed reaction.

Homogeneous catalysis (i·e· those that act in solution rather than, say, at solid surfaces) clearly must participate in the chemistry of the reaction and be regenerated at the formation of the product·

9.1 Acid and base catalysis

1 Acid catalysis   3 Base catalysis
2 A-S_E 2 mechanism
9.1.1 Specific and general catalysis

The kinetics of an acid- or base-catalysis reaction are frequently complex, the empirical rate equation containing several terms.

$$\text{Rate} = [G](k_{H_2O} + k_{H_2O}·[H_3O^+] + k_{AcOH}[AcOH]). \qquad [9.1]$$

This is termed *general acid catalysis* and can be inferred from a plot of rate constant against buffer concentration; as the latter changes, constancy of the hydronium ion concentration is ensured but [AcOH] varies.

$$\text{Rate} = \sum^{acids} k_{HA}[S][HA],$$

Fig. 9.2 Effect of buffer concentration of rates of specific H_3O^+-catalysed and general acid-catalysed reactions.

Similarly, a reaction may be catalysed by all bases present (e.g. H_2O, OH^-, A^-): *general base catalysis,* and it is also possible to have a reaction which is catalysed by both acids and bases.

$$\text{Rate} = \sum^{acids} k_{HA}[S][HA] + \sum^{bases} k_B[S][B]. \qquad [9.2]$$

On the other hand, some reactions respond to catalysis only by hydronium or hydroxide ions (in general, lyonium and lyate ions) and are then deemed to show *specific acid or base catalysis.*

弱酸的催化被忽略

$$S + H^+ \rightleftarrows SH^+;$$

$$SH^+ (+ \text{solvent}) \xrightarrow[\text{slow}]{k} \text{products},$$

$$\text{Rate} = k[SH^+]$$

or, since the acidity of the substrate, $K_A^S = [SH^+]/[S][H^+]$,

$$\text{Rate} = kK_A^S[S][H^+],$$

$$\text{C=C=O} + \text{H}^+ \rightleftharpoons \text{C—C—OH}$$

(S)   (SH⁺)

$$\text{C—C—OH} + \text{A}^- \rightleftharpoons \text{C=C—OH} \xrightarrow{\text{products}}$$

(SH⁺)   (E)   + AH

特殊酸催化 $k_{H2O}/k_{D2O}\sim 1/6$

普通酸催化决速步是质子转移, $k_{H2O}/k_{D2O} \sim 1/6*7$

Rate = k[SH⁺][A⁻]

but $K_A^s = [SH^+]/[S][H^+]$ and [A⁻] = K_A^C[HA]/[H⁺]. Hence

Rate = $kK_A^s K_A^C$[S][HA].

Table 9.1 Examples of acid- and base-catalysed reactions.

Reaction	Type*
Esterification and hydrolysis of carboxylic and phosphoric esters and amides	A, B
Hydrolysis of acetals, ketals and orthoesters	(sp) A
Hydrolysis and alcoholysis of anhydrides	A
Carbonyl condensation reactions with X—NH₂	A, B
Enolization and electrophilic substitution α- to a carbonyl group	A, B
Hydration of alkenes and dehydration of alcohols	A
Additions of CN⁻, HSO₃⁻, H₂O, etc., to >C=O	A, B
Cleavage of C—Hg, C—Sn bonds	A
Decomposition of NH₂NO₂ to N₂O and H₂O	B
Aldol and Michael reactions	B
Aromatic electrophilic proton exchange	A
Beckmann rearrangement	A
Hydrolysis of epoxides	(sp) A, B

* A, acid-catalysed; B, base-catalysed; sp, specific.

Slide 10

9.1.3 Method of distinguishing between A1 and A2 reactions

The Hammett-Zucker postulate

For A1 reactions, catalytic rates should follow H₀ rather than [H₃O⁺] and a plot of k against H₀ should have unit slope. On the other hand, for A2 process,

$$\text{Rate} = k_2[SH^+][H_2O] = k_2\, K[S][H_3O^+] \qquad [9.3]$$

Bunnett's w-values

Plot of (ln k - H₀) against the activity of water, a_{H2O}, to give a slope, w, varying over the range -8 to +7, is measure of this deviation, which has mechanistic significance.

w	Function of water in rate-determining step
-2.5 to 0	Not involved; A1 mechanism,
+1.2 to +3.3	Acts as nucleophile; A–SN2 reaction.
> +3.3	Proton transfer agent; A2 reaction.

Slide 11

The Bunnett and Olsen parameter, φ

$$\log I + H_0 = \phi(H_0 + \log[H^+]) + pK_A. \qquad [9.5]$$

$$\log k + H_0 = \phi(H_0 + \log[H^+]) + \text{constant}. \qquad [9.6]$$

φ	Function of water in rate-determining step
<0	Not involved
+0.22 to +0.56	Acts as nucleophile
> +0.58	Acts as proton-transfer agent

Table 9.4 Examples of Bunnett's w- and φ-parameters.

Reaction	w	φ
A1 reactions: w < 0, φ < 0		
Hydrolysis of MeCH(OEt)₂, HCl, 0 °C	-7.86	-1.02
Paraldehyde → MeCHO, 25 °C	-4.32	-0.58
Hydrolysis of MeCOOCH₂OEt, 25 °C	-3.57	-0.44

9.1.4 Linear free-energy relationships: the Bronsted Catalysis Law

Catalystic rate constants can be expected to increase with increasing strength of acid or bases, and a very good linear relationship between k_{cat} and K_A is known as the **Bronsted Catalysis Law**.

$$k_A = G_A K_A^{\alpha} \quad \text{or} \quad \log k_A = \alpha p K_A + \text{constant}; \qquad [9.7]$$

$$k_B = G_B K_A^{-\beta} \quad \text{or} \quad \log k_B = -\beta p K_A + \text{constant}; \qquad [9.8]$$

Fig. 9.4 Potential curves (energy versus distance) for the systems A–H—B (curve I) and A⁻ ··· H–B⁺ (curve II). BH⁺ is a weaker acid than AH by an amount proportional to σ². The proton transfer proceeds by stretching of the A–H bond until the energy is such that the two curves intersect. Continuation of the motion results in product formation with an energy barrier E°. B'H⁺ is a still weaker acid and the additional activation energy required for proton transfer from HA is δE°, proportional to its difference in pKₐ, δε. The Bronsted relationship shows linearity as long as curve II, H⁺ are parallel.

Fig. 9.5 Schematic relationships between rates of proton transfer between two bases, and their difference in pK_A.[16] As long as pK_A of the proton acceptor is greater than that of the donor, the reaction is diffusion-controlled and the rate is large and constant, independent of the donor strength. At $\Delta pK \sim 0$ there is a change in slope giving a normal Brønsted plot, α, $\beta \sim 1$, as the reverse reaction becomes diffusion-controlled. Carbon acids, c, tend to transfer protons at less than diffusion-controlled rates and may give curved Brønsted plots.

9.1.5 Interpretation of the Bronsted coefficients

The coefficients α and β have the significance of LFER susceptibility parameters and are a measure of the sensitivity of the catalysed reaction to the strength in water of its catalysis as acids and as base respectively.

Assuming the thermodynamic properties of the transition state for a proton transfer to be intermediate between those of reagents and products, a structural change will affect the free energy of the transition state by the amount $\delta G^{\ddagger}$ such that

$$\delta G^{\ddagger} = \alpha\delta G_p + (1 - \alpha)\delta G_r,\qquad\qquad [9.9]$$

where G_p, G_r are free energies of products and regents. Therefore, α is a parameter measuring the position of the transition state on the reaction coordinate.

Table 9.6 Examples of Brønsted coefficients for some acid- and base-catalysed reactions.

2019/11/11   15

9.1.6 Nucleophilic catalysis

The following characteristics enable general base and nucleophilic catalysis to be distinguished.

(a) Catalysis by the leaving group: a general base action; negative catalysis: nucleophilic catalysis   被离去基团催化：普通碱催化；负催化：亲核催化

(b) Reaction with respect to the catalyst in a second order kinetics: a general base action, 6   涉及催化剂的反应呈二级动力学：普通碱催化

(c) non-parallel for base strength and nucleophilic activity at carbon: nucleophilic catalysis   碱强度与在碳上亲核活性的非同向关系：亲核催化

(d) isolated reactive intermediate: nucleophilic catalysis, 9a   分离到活性中间体：亲核催化
2019/11/11   16

9.1.7 Solvent isotope effects

Acid-catalysed reactions are faster in D_2O, and values of k_{H2O}/k_{D2O} =0.3~0.43 for pre-equilibrium protonation; 0.45~1 for concerted reactions.

When proton transfer becomes RDS, a full PKIE
Table 9.8 Some solvent isotope effects in acid-catalysed hydrolyses.

2019/11/11   17

9.1.8 Electrophilic catalysis

The elecrophilic catalyst may release a proton from water (11); it may coordinate with an elecrophilic reagent and increase its electrophilicity (12) or to a nuleophilic leaving group and increase its nucleofugacity (13, 14).

9.2 The mechanisms of some catalysed reactions

9.2.1 Substitution α to a carbonyl group

$$rate = k_{H^+} \cdot [H^+] + k_{AcOH}[AcOH] + k_{OH^-} \cdot [OH^-] + k_{OAc^-} \cdot [AcO^-]$$
$$+ k_{H_2O} + k'[AcOH][AcO^-]$$

for which

$k_{H^+} = 560 \times 10^{-6}\,s^{-1}$
$k_{AcOH} = 1\cdot35 \times 10^{-6}\,s^{-1}$
$k_{OH^-} = 7\,s^{-1}$
$k_{OAc^-} = 3\cdot35 \times 10^{-6}\,s^{-1}$
$k_{H_2O} = 0\cdot006 \times 10^{-6}\,s^{-1}$
$k' = 3\cdot5 \times 10^{-6}\,M^{-1}\,s^{-1}$

(b) Cryptands
(c) Calixarene
(d) Cyclodextrins
---

1 True acid catalysis (in which the catalysing acid is not consumed) must also require the availability of a base. Consider the logic of this statement.

2 A general scheme for acid catalysis is the following:

$$S + HA \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} SH^+ + A^-;$$

$$SH^+ \underset{k_{-2}}{\overset{k_2}{\rightleftharpoons}} PH^+;$$

$$PH^+ + A^- \overset{k_3}{\longrightarrow} P + HA.$$
Derive kinetic expressions for catalysed reactions when
(a) $k_{-1}[A^-] \gg k_2$ and $k_3[A^-] \gg k_{-2}$,
(b) $k_2 \gg k_{-1}[A^-]$.

3 Strong bases promote isomerization of alkenes with a tendency to move double bonds into conjugation. The following isomerizations were carried out in a deuterated solvent and deuterium incorporation was determined:
How may these results be accounted for?

---

4 Sketch out the steps needed to convert ethyl orthocarbonate into CO_2:

$$C(OEt)_4 \overset{H^+ \cdot H_2O}{\rightarrow} \rightarrow CO_2 + 4EtOH.$$
5 Suggest mechanisms for the following catalysed reactions.
(a) Amide dehydration:

(b) The 'abnormal' Beckmann rearrangement:

(c) The Stieglitz rearrangement:
