Received September 14, 1999; in revised form October 14, 1999

The high-resolution Fourier transform spectrum of the D<sub>2</sub>O molecule was recorded in the 3200–4200 cm<sup>-1</sup> region, where the bands of the second triad of interacting vibrational states are located. As a result of the theoretical analysis, both the rotational–vibrational structure of the (011) vibrational state was improved, and the rotational energies of the (110) and (030) vibrational states were determined for the first time up to rotational quantum numbers  $J^{\text{max.}} = 15$  and 14, respectively.  $\otimes$  2000 Academic Press

# 1. INTRODUCTION

The analysis of the vibration–rotation spectra of the deuterated species of water is of great interest for many problems both of pure academic and of applied interest. Such problems, for example, are the investigation of the dynamics of molecular vibrations and rotations, the determination of the intramolecular potential function, atmospheric studies of planets, the study of the role of deuterium in interstellar molecules as an indicator of chemical reactions, the investigation of industrial pollution and of laser techniques, and so on.

The dideuterated water molecule has been the subject of several spectroscopic studies both in the microwave and in the infrared regions [see, e.g., Refs. (1-16)]. As to the second triad of interacting vibrational states (011)-(110)-(030), they were considered earlier in two papers only: in Ref. (1) the vibrational band  $\nu_2 + \nu_3$  was studied with a grating spectrometer at a resolution of 0.25–0.30 cm<sup>-1</sup>; in Ref. (13) the same  $\nu_2 + \nu_3$  band was analyzed with a selective modulation Girard spectrometer achieving a better resolution (0.07 cm<sup>-1</sup>). In the last case, few lines of the weak  $\nu_1 + \nu_2$  band were also assigned.

In the present paper about 2300 transitions belonging to the  $D_2O$  absorption were measured with a high-resolution Fourier transform spectrometer in the 3200–4200 cm<sup>-1</sup> region.

#### 2. EXPERIMENTAL DETAILS

The sample of  $D_2^{16}O$  was purchased from PeKing Chemical Industry, Ltd. (China). The stated purity of deuterium was 99.8%.

Since HDO and  $H_2O$  have strong absorption in the 3200–4200 cm<sup>-1</sup> region in which we were interested,  $D_2O$  samples

<sup>1</sup> To whom correspondence should be addressed. E-mail: ulenikov@ phys.tsu.ru.

mixed with H<sub>2</sub>O at different ratios (see Table 1) were used to facilitate the identification of D<sub>2</sub>O lines. The spectra were recorded with the Bruker IFS 120HR Fourier transform interferometer at Hefei, which was equipped with a multipass gas cell with adjustable path length. A tungsten source, a CaF<sub>2</sub> beamsplitter, an optical band pass filter whose cutoff frequencies were 3200 and 4300 cm<sup>-1</sup>, and a liquid-N<sub>2</sub>cooled InSb detector were used. The unapodized resolution was 0.008 cm<sup>-1</sup>, which is comparable with the Doppler width (about 0.01 cm<sup>-1</sup>) in this region. Because the absorption intensities of the  $\nu_2 + \nu_3$ ,  $\nu_1 + \nu_2$ , and  $3\nu_2$  bands of the D<sub>2</sub>O were quite different, various sample pressures and path lengths have been employed, as detailed in Table 1. The pressures were measured by a pressure gauge with an accuracy better than 1 Pa. All spectra were recorded at room temperature. The signal-to-noise ratios (SNR) varied from 1800 to 3300 (see Table 1), and about 2300 lines with good SNR were supposed to belong to  $D_2O$ . The frequencies were calibrated with those of the HDO lines in that region reported by Toth and Brault (17). The wavenumber precision of not too strong, unblended lines was  $2-5 \times 10^{-4}$  cm<sup>-1</sup>. For illustration, two small pieces of the recorded spectra are presented in Figs. 1 and 2.

# **3. HAMILTONIAN MODEL**

Since all three vibrational states (011), (110), and (030) of the  $D_2O$  molecule are strongly interacting, we used in the analysis the following Hamiltonian model,

$$H^{\text{eff.}} = \sum_{\nu,\nu'} |\nu\rangle \langle \nu' | H_{\nu\nu'}, \qquad [1]$$

band	total pressure	path length	percent	percent	percent	number of scans	SNR
$v_{2}+v_{3}$	33	15	81	18	1	505	2600
	75	15	25	50	25	600	3300
$v_1 + v_2$	292	51	95	5	0.06	520	1800
	860	87	98	2	0.01	500	2600
	527	15	25	50	25	400	2000
$3v_2$	1650	105	98	2	0.01	500	1800
	527	15	25	50	25	400	2000

where the diagonal operators  $H_{\nu\nu}$  ( $\nu = 1, 2, 3$ ) are the usual Watson's operators (18):

$$\begin{split} H_{\nu\nu} &= E_{\nu} + \left[ A^{\nu} - \frac{1}{2} (B^{\nu} + C^{\nu}) \right] J_{z}^{2} + \frac{1}{2} (B^{\nu} + C^{\nu}) J^{2} \\ &+ \frac{1}{2} (B^{\nu} - C^{\nu}) J_{xy}^{2} - \Delta_{K}^{\nu} J_{z}^{4} - \Delta_{JK}^{\nu} J_{z}^{2} J^{2} - \Delta_{J}^{\nu} J^{4} \\ &- \delta_{K}^{\nu} \left[ J_{z}^{2}, J_{xy}^{2} \right] - 2 \delta_{J}^{\nu} J^{2} J_{xy}^{2} + H_{K}^{\nu} J_{z}^{6} \\ &+ H_{K}^{\nu} J_{z}^{4} J^{2} + H_{JK}^{\nu} J_{z}^{2} J^{4} + H_{J}^{\nu} J^{6} \end{split}$$

$$+ \left[J_{xy}^{2}, h_{K}^{\nu}J_{z}^{4} + h_{JK}^{\nu}J^{2}J_{z}^{4} + h_{J}^{\nu}J^{4}\right] + L_{K}^{\nu}J_{z}^{8} + L_{KKJ}^{\nu}J_{z}^{6}J^{2} + L_{KJ}^{\nu}J_{z}^{4}J^{4} + L_{JJK}^{\nu}J_{z}^{2}J^{6} + L_{J}^{\nu}J^{6} + \left[J_{xy}^{2}, l_{K}^{\nu}J_{z}^{6} + l_{KJ}^{\nu}J_{z}^{4}J^{2} + l_{JK}^{\nu}J_{z}^{2}J^{4} + l_{J}^{\nu}J^{6}\right] + P_{K}^{\nu}J_{z}^{10} + Q_{K}^{\nu}J_{z}^{12}.$$

$$[2]$$

Since the (110) and (030) states are of  $A_1$  symmetry and the

**FIG. 1.** A portion of the  $D_2^{16}$ O spectrum in the region of the  $\nu_2 + \nu_3$  and  $\nu_1 + \nu_2$  bands. The first spectrum was measured at a total pressure of 33 Pa (about 80% of  $D_2$ O), with an absorption path length of 15 m; the second one with the conditions of 860 Pa (about 98% of  $D_2$ O) and 87 m. A and B denote the  $\nu_2 + \nu_3$  and  $\nu_1 + \nu_2$  bands, respectively; lines marked with D and H are absorption of HDO and H<sub>2</sub>O in the sample, respectively.

**FIG. 2.** A small fraction of the weak  $3\nu_2$  band of the  $D_2^{16}O$ . The spectrum shown was measured at a total pressure of 1650 Pa (about 98% of  $D_2O$ ), with an absorption path length of 105 m. Lines marked with D and H are HDO and H<sub>2</sub>O absorptions in the sample, respectively. Two lines marked with F belong to H<sub>2</sub>CO.

(011) state is of  $B_1$  symmetry, resonance interaction operators  $H_{\nu\nu'}$  ( $\nu \neq \nu'$ ) were taken in the following form,

$$H_{23} = H_{32}^{+} = F_{0}^{23} + F_{J}^{23}J^{2} + \dots + F_{xyJ}^{23}J_{xy}^{2}$$
  
+  $F_{xyK}^{23}[J_{xy}^{2}, J_{z}^{2}]_{+} + F_{xyJ}^{23}J_{xy}^{2}J^{2} + F_{xyKK}^{23}[J_{xy}^{2}, J_{z}^{4}]_{+}$  [3]  
+  $F_{xvKJ}^{23}[J_{xy}^{2}, J_{z}^{2}]_{+}J^{2} + \dots$ 

for the Fermi-type interaction between the states (110) and (030), and

$$H_{n1} = H_{1n}^{+} = C_{yK}^{n1} [iJ_{y}, J_{z}^{2}]_{+ \dots} + C_{xz}^{n1} [J_{x}, J_{z}]_{+} + C_{xzK}^{n1} [[J_{x}, J_{z}]_{+}, J_{z}^{2}]_{+} + C_{xzJ}^{n1} [J_{x}, J_{z}]_{+} J^{2} \cdots$$
[4]  
+  $C_{yxy}^{n1} [J_{y}, J_{xy}]_{+ \dots}$ 

(n = 2, or 3) for the Coriolis-type interactions between the states (110) or (030), on the one hand, and the (011) state, on the other hand.

In Eqs. [2]–[4] the following notations are used:  $J_{xy}^2 = J_x^2 - J_y^2$  and  $J^2 = \sum_{\alpha} J_{\alpha}^2$ ;  $|1\rangle = (011)$ ,  $|2\rangle = (110)$ , and  $|3\rangle = (030)$ .

# 4. ASSIGNMENT OF TRANSITIONS AND ANALYSIS

Assignments of transitions in the recorded spectra have been made on the basis of the ground state combination differences (GSCD) method. In this case, the ground state energies were calculated on the basis of parameters from Ref. (6) (for convenience of the reader, they are reproduced in column 2 of Table 2). Thanks to the high sensitivity of the spectrometer and the possibility of using a long pathlength, we were able to assign transitions not only of the strong  $\nu_2 + \nu_3$  and weaker  $\nu_1 + \nu_2$  bands (see examples of the recorded spectra on Fig. 1), but also of the very weak  $3\nu_2$  band (see Fig. 2) as well. As a result of the analysis, about 2000 lines in the spectra were assigned, and values of upper state energies, which are presented in columns 2, 5, and 8 of Table 3, were determined. These latter values were determined as the mean of several individual energies obtained from P, Q, and R transitions reaching the same upper state. In this case, only "full quality" transitions were used in the determination of the mean values, namely: (1) unblended, uncovered, and not too strong (only

<sup>*a*</sup> In Table 3  $\Delta$  is the experimental uncertainty of the energy value, equal to one standard deviation in units of 10<sup>-4</sup> cm<sup>-1</sup>;  $\delta$  is the difference  $E^{exp} - E^{ealc}$ , also in units of 10<sup>-4</sup> cm<sup>-1</sup>;  $\Delta$  is not quoted when the energy value was obtained from only one transition (corresponding energies were used in the fit with the weight 1/100).

unsaturated) lines; (2) since the precision of the positions of very weak lines is considerably worse than that of the lines of medium strength, the former were not taken into account in the determination of mean values appearing in columns 2, 5, and 8. The  $\Delta$  value in columns 3, 6, and 9 of Table 3 is the uncertainty of the mean value determined from several such individual energies in units of  $10^{-4}$  cm<sup>-1</sup>.

The obtained upper state energies then were used as the initial data in the procedure of determining the parameters of the Hamiltonian [1]–[4]. It should be mentioned that the as-

signment of the spectral lines and the procedure of the determination of spectroscopic parameters were made at the same time. For this reason we were able to assign without a doubt even such lines in the spectrum which have no counterparts useful for the GSCD method. Such energies (determined only from one single line) are presented in Table 3 without experimental uncertainty.

To determine the spectroscopic parameters of the Hamiltonian [1]–[4], the fit of all experimentally obtained energies from Table 3 was made. In this case, in the upper state fit

TABLE 4 Parameters of Resonance Interactions for the Second Triad (in  $\text{cm}^{-1}$ )<sup>*a*</sup>

Fe	rmi	Coriolis							
Parameter	Value	Parameter	Value						
$F_0^{110-030}$	23.93(167)	$C_{yK}^{110-011}10^4$	-4.585(337)						
$F_J^{110-030} 10^2$	1.533(587)	$C_{xz}^{110-011}10$	1.78558(362)						
$F_{xy}^{110-030}10^2$	-4.713(707)	$C_{xzK}^{110-011}10^4$	-0.8333(216)						
$F_{xyK}^{110-030}10^4$	8.61(122)	$C_{xz}^{030-011}10$	-0.2344(359)						
$F_{xyJ}^{110-030}10^4$	1.055(178)	$C_{xzK}^{030-011}10^4$	4.189(231)						
$F_{xyKK}^{110-030}10^{6}$	-8.898(939)	$C_{xz,J}^{030-011}10^4$	0.3425(874)						
$F_{xyKJ}^{110-030}10^6$	-0.929(167)	$C_{yxy}^{030-011}10^4$	-0.3645(786)						

<sup>*a*</sup> See footnote to Table 2.

(determination of the parameters of the Hamiltonian) energies were used with the weights equal to  $(10/\Delta)^2$  ( $\Delta$  in units of  $10^{-4}$  cm<sup>-1</sup>). This means that levels with  $\Delta = 10 \times 10^{-4}$  cm<sup>-1</sup> were unit-weighted. When the upper energy was obtained only from one single transition, it was given the weight of 1/100 (using the weight of 1/100 for such energies looks like a suitable procedure because the results of a fit, on the one hand, faintly depend on them and, on the other hand, indicate quality of a prediction power of a fit). The results of the fit are presented in columns 3–5 of Table 2. The values in parentheses in this table are the 1 $\sigma$  statistical confidence intervals for corresponding spectroscopic parameters in the last digits.

It should be mentioned that the presence of strong resonance interactions between all three bands of the second triad allowed us to determine stable values of resonance interaction parameters which are presented in Table 4. Such strong resonance interactions already appear in the spectrum for small values of the quantum number J. As an illustration, one can see an irregular rotational structure of the (110) vibrational state beginning already at a J value of J = 6.

We believe that the obtained parameters are correct because: (1) They reproduce the experimental energies with accuracies close to the experimental uncertainties. This statement is confirmed by the  $\delta$  values in columns 4, 7, and 10 of Table 3, which are the differences between experimental energy values in units of  $10^{-4}$  cm<sup>-1</sup> and those calculated with the parameters of Tables 3 and 4. Slightly larger than usual values of the  $\delta$  for some of the [*JJ*0] and [*JJ*1] rotational states of the (011) vibrational state (see column 4 of Table 3) can be explained by

## 5. CONCLUSION

The analysis of the high-resolution Fourier transform spectra of the  $D_2O$  molecule carried out in the framework of the Hamiltonian model which takes into account resonance interactions between the states (011), (110), and (030) allowed us to improve considerably the knowledge of the rotational vibrational structure of the (011) state. For the first time we were able to determine rotational energies of the (110) and (030) vibrational states with values of quantum number *J* up to 15 and 14, respectively.

#### ACKNOWLEDGMENTS

This work was supported by the Chinese National Science Foundation, the Chinese Academic of Sciences, the Chinese Pan-Deng Project, and the National Natural Science Youth Foundation of China. O. N. Ulenikov thanks University of Science and Technology of China for a visiting professorship, and G. Onopenko thanks the Ru Jia-xi Foundation for financial support during her stay in Hefei in April–June, 1999.
