**Abstract** The locally twisted cube  $LTQ_n$  is a newly introduced interconnection network for parallel computing. As a variant of the hypercube  $Q_n$ ,  $LTQ_n$  has better properties than  $Q_n$  with the same number of links and processors. Yang, Megson and Evans [Locally twisted cubes are 4pancyclic, Applied Mathematics Letters, 17 (2004), 919-925] showed that  $LTQ_n$  contains a cycle of every length from 4 to  $2^n$ . In this note, we improve this result by showing that every edge of  $LTQ_n$  lies on a cycle of every length from 4 to  $2^n$  inclusive.

Keywords Cycle, Locally twisted cubes, Pancyclicity, Edge-pancyclicity

AMS Subject Classification: 05C38 90B10

### 1 Introduction

The architecture of an interconnection work is usually represented by a connected simple graph G = (V, E), where the vertex-set V is the set of processors and the edge-set E is the set of communication links in the network. The edge connecting two vertices x and y is denoted by (x, y). A graph G is weakly pancyclic if it contains cycles of all lengths from 4 to |V| in G. The pancyclicity is an important measurement to determine if a topology of network is suitable for an application where mapping rings of any length into the topology of network is required. Large amount of related work appeared in the literature [3, 4, 5]. Vertex-pancyclicity and edge-

<sup>1</sup> 

pancyclicity are two stronger pancyclic properties. A graph G is weakly vertex(edge)-pancyclic if, for each vertex(edge) and any integer l ranging from 4 to |V|, there is a cycle of length l containing the vertex(edge). It is clear that a weakly edge-pancyclic graph is also a weakly vertex-pancyclic graph. Vertex-pancyclicity and edge-pancyclicity of some graphs have been discussed [6, 7, 8].

The hypercube network  $Q_n$  has proved to be one of the most popular interconnection networks since it has a simple structure and is easy to implement. As a variant of  $Q_n$ , the locally twisted cube  $LTQ_n$ , proposed by Yang *et al* [1], has many properties superior to  $Q_n$ . For example,  $LTQ_n$ has about half of the diameter of  $Q_n$  [1]. In particular, Yang *et al* [2] proved that  $LTQ_n$  contains a cycle of length from 4 to  $2^n$ . In this note, we improve this result by showing the following theorem.

**Theorem** Every edge of  $LTQ_n$  lies on a cycle of every length from 4 to  $2^n$  inclusive for  $n \ge 2$ .

The proof of the theorem is in Section 3. In Section 2, the definition and basic properties of  $LTQ_n$  are given.

#### 2 Locally Twisted Cubes

An *n*-dimensional locally twisted cube  $LTQ_n (n \ge 2)$ , proposed first by Yang *et al* [1], has  $2^n$  vertices. Each vertex is an *n*-string on  $\{0, 1\}$ . Two vertices  $x = x_1 x_2 \dots x_n$  and  $y = y_1 y_2 \dots y_n$  are adjacent if and only if one of the following conditions are satisfied.

(1) There is an integer  $1 \le k \le n-2$  such that

(a)  $x_k = \bar{y}_k$  ( $\bar{y}_k$  is the complement of  $y_k$  in  $\{0, 1\}$ ),

(b)  $x_{k+1} = y_{k+1} + x_n$ , and

(c) all the remaining bits of x and y are identical.

(2) There is an integer  $k \in \{n-1, n\}$  such that x and y differ only in the  $k^{th}$  bit.

According to the above definition, it is not difficult to see that  $LTQ_n$ can be recursively defined as follows.  $LTQ_2$  is a graph consisting of four vertices labelled with 00, 01, 10, and 11, respectively, connected by four edges (00, 01), (00, 10), (10, 11) and (01, 11). For  $n \geq 3$ ,  $LTQ_n$  is constructed from two disjoint copies of  $LTQ_{n-1}$  by adding  $2^{n-1}$  edges as follows. Let  $LTQ_{n-1}^0$  denote the graph obtained by prefixing the label of each vertex of one copy of  $LTQ_{n-1}$  with 0, let  $LTQ_{n-1}^1$  denote the graph obtained by prefixing the label of each vertex of the other copy of  $LTQ_{n-1}$  with 1, and connect each vertex  $x = 0x_2x_3...x_n$  of  $LTQ_{n-1}^0$  with the vertex  $1(x_2+x_n)x_3...x_n$  of  $LTQ_{n-1}^1$  by an edge, where '+' represents the modulo 2 addition. For short, we denote  $LTQ_n = L \oplus R$ , where  $L \cong LTQ_{n-1}^0$  and

2

 $R \cong LTQ_{n-1}^1$  and call edges between L and R cross edges. Moreover, we write a cross edge as  $(u_L, u_R)$ , where  $u_L \in L$  and  $u_R \in R$ .

We use  $LTQ_{n-2}^{ij}$  to denote the (n-2)-dimensional locally twisted cube which is a subgraph of  $LTQ_n$  induced by the vertices labelled  $ijx_3 \ldots x_n$ . We say an edge of  $LTQ_n$  to be critical if it is an edge in  $LTQ_{n-1}^i$  with one endpoint in  $LTQ_{n-2}^{i0}$  and the other in  $LTQ_{n-2}^{i1}$  for  $i \in \{0, 1\}$ .

**Lemma 1** Let  $LTQ_n = L \oplus R$  with  $n \ge 3$ . If  $(u_L, v_L) \in E(L)$  is a critical edge of  $LTQ_n$ , then  $(u_R, v_R) \in E(R)$  is also a critical edge of  $LTQ_n$ , where  $u_R$  and  $v_R$  are the neighbors of  $u_L$  and  $v_L$  in R, respectively.

Proof Suppose that  $(u_L, v_L) \in E(L)$  is a critical edge of  $LTQ_n$  and, without loss of generality, assume that  $u_L = 00u_3u_4...u_n$ . We have  $v_L = 01(u_3 + u_n)u_4...u_n$ ,  $u_R = 1(0 + u_n)u_3u_4...u_n$  and  $v_R = 1(1 + u_n)(u_3 + u_n)u_4...u_n$ . By definition of  $LTQ_n$ ,  $u_R$  and  $v_R$  are adjacent, hence  $(u_R, v_R)$  is a critical edge in R.

Note that if  $LTQ_n = L \oplus R$ , then, for any two adjacent  $u_L$  and  $v_L$ in L, their neighbors  $u_R$  and  $v_R$  in R are not always adjacent in R, and vice versa. However, it is clear from Lemma 1 that if  $(u_L, v_L)$  is a critical edge, then their neighbors  $u_R$  and  $v_R$  in R must be adjacent in R, and vice versa. Thus, the vertices  $u_L, v_L, v_R, u_R, u_L$  form a 4-cycle. Critical edges play an important role in the proof of our theorem. A cycle in  $LTQ_n$  is called a 2-critical if it contains at least two critical edges. It is easy to see that every vertex in  $LTQ_n$  is incident with a critical edge and every cross edge lies on a 2-critical cycle of length four.

**Lemma 2** If the length of a cycle is greater than  $2^{n-2}$  in the subgraph  $LTQ_{n-1}^0$  of  $LTQ_n$  for  $n \ge 4$ , then it must be a 2-critical cycle.

Proof Note that the (n-2)-dimensional crossed cube  $LTQ_{n-2}^{0j}$  for  $j \in \{0,1\}$  has only  $2^{n-2}$  vertices. Since any cycle in  $LTQ_{n-2}^{00}$  or in  $LTQ_{n-2}^{01}$  has length at most  $2^{n-2}$ , any cycle of length greater than  $2^{n-2}$  in  $LTQ_{n-1}^{01}$  must contain vertices in both  $LTQ_{n-2}^{00}$  and  $LTQ_{n-2}^{01}$  and so contain at least two critical edges between  $LTQ_{n-2}^{00}$  and  $LTQ_{n-2}^{01}$ .

## 3 Proof of Theorem

In this section, we give the proof of Theorem stated in Introduction.

**Proof** We prove the theorem by induction on  $n \ge 2$ . The theorem is true for n = 2.

For n = 3, by the symmetric property of  $LTQ_3$  (see Fig. 1), we only need to show that the theorem holds for the edge  $e \in \{(000, 001), (010, 000)\}$ .

#### 3

Figure 1: (a)An ordinary drawing of  $LTQ_3$  (b) a symmetric drawing of  $LTQ_3$ 

All cycles of lengths from 4 to 8 containing (000, 001) (labelled by underlines) and (010, 000) (labelled by overlines) are as follows.

- (1) length 4:  $\langle 000, 001, 011, \overline{010, 000} \rangle$ ;
- (2) length 5:  $\langle 000, 001, 111, 110, \overline{010, 000} \rangle$ ;
- (3) length 6:  $\langle 000, 001, 111, 101, 011, \overline{010, 000} \rangle$ ;
- (4) length 7:  $(000, 001, 111, 101, 100, 110, \overline{010}, 000)$ ;
- (5) length 8:  $\langle 000, 001, 111, 110, 100, 101, 011, \overline{010, 000} \rangle$ ;

Hence, the theorem is true for n = 3.

Assume now that the theorem is true for all  $3 \le k < n$ . Let e be any edge of  $LTQ_n$  and let  $\ell$  be any integer with  $4 \le \ell \le 2^n$ , where  $n \ge 4$ . To complete the proof of the theorem, we need to show that e is contained in a cycle of length  $\ell$  by considering two cases according as e is a cross edge or not.

Case 1. The edge e is not a cross edge. Then the edge e is in L or R. Without loss of generality, we may assume e is in L.

If  $4 \leq \ell \leq 2^{n-1}$ , by the induction hypothesis, there exists a cycle of length  $\ell$  in  $L \subset LTQ_n$  that contains e.

Suppose that  $2^{n-1} + 1 \leq \ell \leq 2^{n-1} + 3$ . By the induction hypothesis, there exists a cycle C of length  $2^{n-1} - 3$  in L containing e. For  $n \geq 4$ , we have  $2^{n-1} - 3 > 2^{n-2}$ , and so C is a 2-critical cycle by Lemma 2. Thus, we can choose a critical edge  $(u_L, v_L)$  in C different from e. Then the neighbors of  $u_L, v_L$  are  $u_R, v_R$  in R with  $(u_R, v_R) \in E(R)$  by Lemma 1. By the induction hypothesis, there exists a cycle C' of length  $4 \leq \ell' \leq 6$  in R containing  $(u_R, v_R)$ . Thus  $P' = C' - (u_R, v_R)$  is a path between  $v_R$  and  $u_R$  in R. Let  $P = C - (u_L, v_L)$ . Then P contains e and  $P + (v_L, v_R) + P' + (u_R, u_L)$  is a cycle of length  $\ell$  in  $LTQ_n$  containing e(see Fig. 2 (a)).

Suppose that  $2^{n-1} + 4 \leq \ell \leq 2^n$ . Let  $\ell' = \ell - 2^{n-1}$ . Then  $4 \leq \ell' \leq \ell'$ 

 $2^{n-1}$ . By the induction hypothesis and Lemma 2, there exists a 2-critical cycle C of length  $2^{n-1}$  in L containing e. We can choose a critical edge  $(u_L, v_L)$  different from e. Without loss of generality, let  $u_R$  and  $v_R$  be the neighbors of  $u_L$  and  $v_L$ , respectively. Then  $u_R$  and  $v_R$  are adjacent in R. Let  $P = C - (u_L, v_L)$ . Obviously e lies on P. By the induction hypothesis there exists a cycle C' of length  $\ell'$  in R that contains  $(u_R, v_R)$ . Let  $P' = C' - (v_R, u_R)$ . Then  $P + (v_L, v_R) + P' + (u_R, u_L)$  is a cycle of length  $\ell$  in  $LTQ_n$  and contains e (see Fig. 2 (b)).

Figure 2: Illustrations for the proof of Theorem

Case 2. The edge e is a cross edge between L and R. We may assume  $e = (u_L, u_R)$  and  $u_L = 0u_2u_3 \dots u_n$ . Then  $u_R = 1(u_2 + u_n)u_3 \dots u_n$ 

The cycles of length 4 and 5 containing e are as follows.

Let  $v_L = 0\bar{u}_2(u_3 + u_n) \dots u_n$ , and  $v_R = 1(\bar{u}_2 + u_n)(u_3 + u_n) \dots u_n$ , then  $(u_L, v_L)$  and  $(u_R, v_R)$  are critical edges and  $\langle u_L, v_L, v_R, u_R, u_L \rangle$  is a cycle of length four in  $LTQ_n$  containing e. And if  $u_n = 0$ 

 $\langle 0u_2u_3...u_n, 0u_2u_3...\bar{u}_n, 1(u_2+\bar{u}_n)u_3...\bar{u}_n, 1(u_2+\bar{u}_n)u_3...u_n, 1(u_2+u_n)u_3...u_n, 0u_2u_3...u_n \rangle.$ 

is a cycle of length five in  $LTQ_n$  containing e.

If  $u_n = 1$ 

$$\langle 0u_2u_3...u_n, 0u_2u_3...\bar{u}_n, 1(u_2+\bar{u}_n)u_3...\bar{u}_n, 1(u_2+u_n)u_3...\bar{u}_n, 1(u_2+u_n)u_3...u_n, 0u_2u_3...u_n \rangle.$$

is a cycle of length five in  $LTQ_n$  containing e.

For  $\ell \geq 6$ , we can write  $\ell = \ell_1 + \ell_2$  where  $\ell_1 = 2, \ell_2 \geq 4$  or  $\ell_1 \geq 4, \ell_2 \geq 4$ . Consider the cycle  $\langle u_L, v_L, v_R, u_R, u_L \rangle$  of length four in  $LTQ_n$  containing e. By the induction hypothesis, there exists a cycle C of length  $\ell_1$  in L containing  $(u_L, v_L)$  if  $\ell_1 \geq 4$  and exists a cycle C' of length  $\ell_2$  in R containing  $(u_R, v_R)$ . Let  $P = (u_L, v_L)$  if  $\ell_1 = 2$  or  $P = C - (u_L, v_L)$  if  $\ell_1 \geq 4$ ;  $P' = C' - (v_R, u_R)$ . Then  $P + (v_L, v_R) + P' + (u_R, u_L)$  is a cycle of length  $\ell$  in  $LTQ_n$  and contains e (see Fig. 2 (c)).

By the induction principle, the theorem follows.
